Grinberg, G. A., and Borodell, B. E. Elements of an exact theory of the wave field of transmission lines. Akad. Nauk SSSR, Zurnal Tekhn. Fiz. 24, 67-95 (1954). (Russia)

The author treats the problem of propagation of electromagnetic waves along a circularly cylindrical wire parallel

to the (plane) earth's surface. The dielectric constant and conductivity of the wire and of the earth are arbitrary. It is immediately assumed, however, that the radius of the wire is much smaller than its elevation above the earth; the effect of the earth is taken as a perturbation and only the first order effect is included. In this manner the effective parameters (series impedance and shunt admittance per unit length) of this transmission line operating in the dominant mode are calculated. The calculation is repeated with the earth, instead of being represented by a semi-infinite medium of large refractive index, introduced into the problem through skin-effect type boundary conditions at its surface. The numerical results of the simplified calculation agree well with those of the more rigorous one.

BONSHTEDT, B.Ye.

✓ Bonstedt, B. E. A method of finding a wide class of electrostatic and magnetic fields for which the solutions of the basic equation of electron optics are expressed by means of known functions. Z. Tehn. Fiz. 25, 541-543 (1955). (Russian)

This method of finding the conditions under which the paraxial ray equation can be readily solved is based on the use of invariants of ordinary linear second-order differential equations and of the Schwarzian derivative [cf., e.g., E. L. Ince, Ordinary differential equations, p. 394, Longmans-Green, London, 1927]. The invariant of the paraxial ray equation is

$$I_r(x) = \frac{q^2}{k} (\varphi''/ \varphi)^2 + \frac{1}{k} (e/m) H^2(x) / \varphi(x),$$

where  $\varphi(x)$  is the electrostatic potential and  $H(x)$  the magnetic field intensity. Given two ordinary linear second-order differential equations whose solutions are known, the method shows: 1. How to use these solutions to determine a function which will be a solution of a paraxial ray equation. 2. How to determine  $\varphi(x)$  and  $H(x)$  from the invariants of the auxiliary equations. Examples are given where the solutions of the two auxiliary equations are Bessel functions of different orders and also where they are Legendre functions of different orders. (A misprint occurs in Eq. (4) whose first term should read  $\frac{1}{k} \xi'''/\xi'$ ). *J. I. Rosenthal*

SUBJECT USSR / PHYSICS  
AUTHOR BONSTEDT, B.E., DMITRIJEW, T.G., ZUCKERMAN, I.I.  
TITLE The Computation of the Reactivity of the Electron Optic Trans-  
former with Homogeneous Fields.  
PERIODICAL Žurn.techn.fis, 26, fasc.9, 1966-1968 (1956)  
Issued: 10 / 1956 reviewed: 10 / 1956

De VORE and WENDT computed the distribution of the density of the current in the electron image. This computation was made for a plane in which the GAUSS image is produced by electrons with the initial energy of zero. In reality, however, the accuracy of the image obtained in this manner may be far from the optimum. The reactivity of the electron optic system of the transformer will in any case be higher if in the screen plane the paraxial electron bundles are not focussed with the initial zero energies but with the most probable energies. In this connection an error was committed in the course of the computations carried out by De VORE and WENDT, and it is the purpose of the present work to point out the essential importance of this error. An approximated computation of the distribution of current density in that plane was made in which the paraxial photo electron bundle was focussed with the most probable initial energy. In the course of computation the same distribution functions with respect to the angles and initial energies were assumed to exist as was the case in the works by De VORE and WENDT. In the case which was examined by De VORE and WENDT, i.e. with  $\epsilon = 0$  ( $\epsilon$  is the initial energy), it is possible to obtain an analytical expression and to carry out the further work of computation analytically. In the case of  $\epsilon_0 \neq 0$  computation cannot be continued analytically, and therefore it was

Zurn.techn.fis, 26, fasc.9, 1966-1968 (1956) CARD 2 / 2

PA - 1401

carried out as an approximated numerical computation. For the purpose of comparing results with those obtained by de VORE and WENDT the so-called modulation coefficient of current density was computed and the results obtained were plotted as curves. The modulation coefficient  $M$  was expressed by the functions of the dimensionless parameter  $\alpha\delta$ , where  $\alpha = \frac{H}{21.2} \sqrt{\frac{V}{V_0}}$ .  $H$  is the voltage of the

magnetic field in oersted.  $V$  is the difference of the potentials of the screen and the photocathode in volts;  $V_0$  is measured in volts. The same drawing also showed the results obtained by De VORE and WENDT which were also plotted as curves, and it was found that the error occurs with particular distinctness in the case of small values of  $\alpha\delta$ , as e.g. when small details of the image are being looked at or when errors are relatively insignificant.

The following may serve as a characteristic example: For the dissection of the electron image transmitted by the television tube of the type Superortikon, the parameter  $\alpha\delta$  is of the order of magnitude 0,2 for small details corresponding to 600 lines of television dissection. The modulation coefficient  $M$ , computed according to the method developed by De VORE and WENDT, will be about 0,04. This is so low a value that the reproduction of such details of an image would be practically impossible. The new computation results in a credible quantity  $M$  of the order 0,3 while the value of  $\alpha\delta$  is the same.

TITLE: Factors Limiting the Resolving Power of a Screen-Type Picture Intensifier  
(O faktorakh, ogranichivayushchikh razreshayushchuyu sposobnost' usilitelya  
izobrazheniya na setkakh)

PERIODICAL: Tekhn. televideniya, 1956, Nr 19, pp 3-16

ABSTRACT: The principle of screen-type brightness-intensifying stages is set forth, based on a secondary-electron amplification of photoelectric current; a historical sketch is presented. The resolving power of a screen-type picture intensifier is limited largely by these three factors: (1) inaccurate registration of the pictures obtained from the photocathode and the preceding stages; (2) focusing errors associated with the spread of initial electron velocities; (3) structure of the screen, whose meshes are comparable with fine elements of the picture. The conditions of registration and simultaneous focusing of a picture in a 1- and 2-stage picture intensifier are considered. Focusing errors associated with a secondary-electron initial-velocity spread are examined.

Card 1/3

112-57-7-15596

Factors Limiting the Resolving Power of a Screen-Type Picture Intensifier

The upper limit of the resolving power of a screen-type intensifier stage is evaluated. A screen pitch of 50-30 microns is recommended. Screens with 30 lines/mm were used for experimental devices. The photocathode-screen distance adopted was 42 mm; the distance between the electrical screen and the viewing screen was 84.5 mm. About 1-kv voltage was necessary for focusing, and willemite was used as a phosphor. To determine the resolving power, the converter tube was placed in a uniform magnetic field of 150 oersteds. With optimum values of magnetic and electric fields selected, pictures on the screen could be fairly well registered, and up to 5 black-white lines/mm could be discerned. In all converter tubes, a bright, luminous background was observed along with a well-focused picture. The resolving power of a 2-stage intensifier with closely placed screens was investigated experimentally and found to be lower than that of a 1-stage intensifier. Fundamental ways to increase the resolution of a picture intensifier are: (1) development of an efficient emitter which would have a much lower spread in secondary-electron initial velocities;

Card 2/3

112-57-7-15596

Factors Limiting the Resolving Power of a Screen-Type Picture Intensifier

(2) use of considerably higher electric and magnetic field strengths.

TITLE: Calculation of the Electrostatic Field of an Aperture System  
(Raschet elektrostaticheskogo polya sistemy diafragm)

PERIODICAL: Zhurnal tekhnicheskoy fiziki, 1958, Nr 8, pp. 1801 - 1808  
(USSR)

ABSTRACT: In this paper a method for the computation of the potential of a system of coaxial apertures is presented. Infinite planes with coaxial circular apertures are placed in a parallel arrangement to represent the system under investigation. The distances between the apertures are comparable with the diameter of the apertures. This method is principally that of joining ("sshivaniye") the solutions presented as integrals. Thus also systems of cylinders with apertures with the diameters of the cylinders considerably in excess of the diameter of the apertures are accessible to calculation. In the second section a sample problem is given illustrating the method exposed in this paper. This incorporates the formulae for the potential field along the axis of an immersion objective of three apertures and the computation of the coefficients contained in

TITLE: Calculating the aberrations in cathode lenses

SOURCE: Radiotekhnika i elektronika, v. 9, no. 5, 1964, 844-850

TOPIC TAGS: cathode lens, cathode lens aberration, electron optics, immersion lens, electron image

ABSTRACT: Formulas for the coefficients of aberration of a combination electromagnetic cathode lens, developed by Yao Fu-Den (Scientia Sinica, 1958, 7, 1, 31), are claimed to be in error. Nearly the same method of developing these formulas is used in the present article; the formulas are intended for calculating the third-order aberrations in combination cathode lenses; the trajectory equation solutions are expanded in small initial electron energies. In addition, the spread of the velocity axial components is analyzed. The formulas allow for

Card 1/2

TITLE: Effect of the resistance of photocathodes on the operation of photoelectric devices for registering large luminous fluxes under conditions of transient switching

SOURCE: Radiotekhnika i elektronika, v. 11, no. 8, 1966, 1477-1483

TOPIC TAGS: photocathode, photoelectric device, photocathode resistance, luminous flux

ABSTRACT: Limitations caused by a semitransparent photocathode when registering strong luminous fluxes are investigated. An analysis of the operation of a photocathode is presented and a method of calculating the longitudinal resistance of the photolayer is proposed. The results of the calculations are confirmed by a number of experimental investigations made with devices produced both in series and in special runs.

Alumina hydrate from nepheline pegmatites of the Vishnevye Mountains (Mid Ural). B. M. Dugdalevitch, Kupetskaya, Zapiski Vserossijskogo Mineral. Obschestva (Mém. soc. russe minéral.) [2] 76, 239-48 (1947).—In the Kurochkin Valley, gibbsite and boehmite occur in fine-granular aggregates in lenses and veins of reddish natrolite, which contain brown Fe oxide hydrate, mica, and fan-shaped diaspore. Individual crystals of boehmite previously described by B. and Vladavets (C.A. 40, 70859) are in secondary calcite. Halloysite encloses all the previous minerals. Other similar occurrences on Mt. Kurochkin and Mt. Karaval are described. Tabular crystals of gibbsite and microscopic grains of boehmite occur with a little apatite in white halloysite in a pegmatite vein of Chubrinov Valley. For all these occurrences, the hydrothermal change of nepheline to natrolite and Al oxide hydrates is, in two principal stages, distinguished by different temps. These paragenetic conditions are in agreement with the hydrothermal alteration of nepheline rocks of Southern Norway and with the formation of kauxites in the Ilmen Mts. Calcite is typical for the crystals of macroscopic boehmite. Crystallographic data, optical properties, and chem. analyses are given for gibbsite and boehmite. Thermal analysis gave a typical curve for gibbsite with an endothermic effect at 650° (transition to monohydrate). After calcination at 1050°, gibbsite is changed to isotropic  $\gamma$ -alumina. Boehmite shows in its dehydration product a tabular meta-phase, biaxial neg.,  $2V = 54^\circ$ ;  $\gamma = 1.587$ ;  $\beta = 1.582$ ; orientation  $a = b$ ,  $b = c$ ;  $\gamma = a$ . The x-ray powder diagram of this product is wholly different from those of all known  $\text{Al}_2\text{O}_3$  modifications.

V Ilmenite from mineral deposits of the Soviet Union. R. M. Bonshtedt-Kunleitskaya. *Trudy Mineralog. Museya Akad. Nauk SSSR*, No. 4, 122-9 (1952).—Chem. analyses and microscopic investigations of polished sections are given for three typical ilmenites from Sta. Mauk, the Poldnevaya Village (Ural), and Praskov'e-Evgenievskaya Mines (Ural), especially in their very characteristic unmixing structures, with fine dispersion of graphic or chainlike intergrowths of magnetite, hematite (martite, from oxidized magnetite), and even rutile. While normal ilmenites only contain moderate percentages of MnTiO<sub>4</sub> and MgTiO<sub>4</sub>, the mineral from Praskov'e-Evgenievskaya Mines contains 62-8% Mg-TiO<sub>4</sub> and 32-35.5% FeTiO<sub>4</sub> (besides 3-10% MnTiO<sub>4</sub>); it is equiv. to "picrolilmenite," d. 4.28. The mineral is also locally replaced by perovskite. An ilmenite from pegmatite veins of Bektau-Ata (northwest Pribalkhash'e) is remarkable because of its distorted forms, elongated along an axis of the hind kind which make it similar to columbite or wolframite. Its Mn content is high ( $10 \pm 2\%$  Mn<sub>2</sub>O<sub>3</sub>). In polished sections the mineral shows an extensive decompr.; only small remnants of primary ilmenite are interspersed in a granular aggregate of hematite and rutile and a nonore mineral (probably mica). The x-ray powder diagram confirms this remarkable disintegration of an ilmenite. W. Eitel

Title : Vinogradovite -- A New Mineral

Orig Pub : Dokl. AN SSSR, 1956, 109, No 3, 617-620

Abstract : In 12 pegmatite cores of Lovozersk and Khibiny alkaline massifs (Kola peninsula) has been discovered a new mineral -- vinogradovite, named in honor of academician A.P. Vinogradov. The mineral is present in the form of finely acicular and finely fibrous formations up to 5 cm in size: in contact-adjoining portions as fringes and pseudomorphoses of ramsaite and lamprophillite; in the central part, within cavities of druses of natrolite and analcime; other associated minerals of pegmatite: aegirite, nepheline, microcline, eudialite, apatite, polylythionite, neptunite etc. Origin of vinogradovite is hydrothermal. Syngony is monoclinic. Coloration of aggregates is white, crystals are colorless. Brittle, with uneven fracture, perfect cleavage along (010). Hardness ~ 4, sp. gr. 2.878, m.p. ~ 800°. Optically biaxial

Effect of vasodilator substances on experimental renal hypertension in rats. F. Herr, L. György, J. Törzsák, and J. Minta (*Acta physiol Acad. Sci. hung.*, 1953, 4, 355-361).—Papaverine, Verparin, Theophylline, Doryl, Yohimbine, N 239 (*p*-bromo-benzyl-mandelyl-tropinium Br) diminish the blood pressure of renal hypertensive rats in small doses, although they have no effect on the normal blood pressure of rats. Veratrine in small doses 0.2 mg./kg. has no effect on the blood pressure, in larger ones 0.5 mg./kg. it causes a great fall in blood pressure both in normal as well as in hypertensive rats. Veratrine-methyl-iodide and veratrine-benzylbromide have no effect on blood pressure. Yohimbine and N 239 have an increasing depressive action with the increase in blood pressure. CO<sub>2</sub> inhalation depresses (after an initial elevation) the blood pressure of hypertensive rats. Sevonal has no depressant action.  
A. B. L. Dezsák.

BONTEA (VERA). Quelques Micromycètes de Roumanie. [Some Rumanian micro-fungi.]—Bull. Sect. sci. Acad. roum., xxiv, 5, pp. 321-330, 1941. [Received April, 1948.]

This list of microfungi collected in Rumania comprises 59 fungi (of which 51 are Uredinales) found on 69 hosts. Among those new to the country are *Septoria caraganae* [R.A.M., xxi, p. 406] on leaves of *Caragana arborescens* and *Uromyces betae* on beet leaves, while others, found on new hosts for Rumania, include *U. genistae-tinctoriae* on *C. arborescens* and *Tranzschelia [Puccinia] pruni-spinosae* on *Prunus cerasifera*. In addition, the following may be mentioned: *Apiosporium [Sclerotium] salicinum* on plum, *Gymnosporangium juniperinum* [ibid., xxv, p. 185] on apple, and *G. sabinae* [ibid., xxv, p. 493] on pear leaves.

R.J.A.M. 1947-67  
125

BONTEA (VRNA). *Micromycetes parasites, nouveaux pour la Roumanie.* [Parasitic microfungi new to Rumania.] - *Bull. Soc. sci. Acad. rom.*, xxv, 7, pp. 435-442, 7 figs., 1943. [Received April, 1948.]

Detailed notes are given on the following fungi in Rumania [cf. *R.A.M.*, xxvii, p. 274]: *Cercosporina* [*Cercospora*] *anethi* [ibid., xxv, p. 439], *Phoma anethi*, [loc. cit.], and *Sporoderrium pluriseptatum* [loc. cit.; xxv, p. 582]. The first was found on *Anethum* [*Piceidium*] *graveolens* on sale in the Bucharest market in the autumn of 1942. The fungus forms dark brown stripes on the leaves, stems, and inflorescences, resembling at first a rust. The pustules when open assume a greyish, velvety appearance. The conidiophores, arising from a spherical pseudostroma, are rigid, sinuous, denticulate, unicellular, olivaceous at the base, hyaline towards the apex, and measure 75 by 6  $\mu$ . The hyaline, straight or slightly curved, cylindrical-fusiform conidia are rounded at the extremities, mostly uniseptate, and measure 21 to 51 by 4 to 7  $\mu$ . Synonyms given are *Marssonina kirchneri* [ibid., ix, p. 613] and *Fusicladium depresso* f. *petrocellini* Moesz [ibid., xvi, p. 493]. Examination of the Moesz herbarium material showed the latter to be identical with the author's fungus.

*Phoma anethi* was found in association with *C. anethi* [ibid., xvii, p. 771]. The isolated, spherical or somewhat flattened pycnidia occurred in an elongated, rather undeveloped, blackish stroma between the ridges on the stem. They were 90 to 180  $\mu$  in diameter, having a 3- to 4-layered wall and a not very prominent, papillate orifice. The hyaline pycnospores measured 2.5 by 1 to 1.5  $\mu$ . It is distinguished from several other *P.* spp. found on the same host by smaller, non-guttulate spores.

*S. pluriseptatum* caused severe leaf spot and leaf curl of cucumber plants at Rasnov in 1942, the leaves drying up and the stems wilting; the entire planting appeared scorched, and the yield was reduced. The conidiophores measured 30 to 45 by 5 to 6  $\mu$  and the conidia from 21 to 66 by 9 to 16  $\mu$ .

All these diseases should be treated by removing and burning the infected plants and practising a three or four years' rotation.

R.J.A.M.

BONTEA (VERA). *Revista fitopatologica din 1942*. [Phytopathological notes for 1942.]—*Anal. Inst. Cerc. agron. România*, xv, p. 208, 1945.

According to an abstract of a paper read before the Rumanian Institute of Agricultural Research in January, 1943, sharp attacks of *Cladosporium cucumerinum* on cucumber, leaf mould of tomato (*Cladosporium fuligineum*), and *Fusarium* wilt of cineraria were noted in Rumania in 1942. *Sporoderrium* [*mucosum* var.] *pluripectatum* was serious on cucumber leaves; the association of *Cercosporina anethi* and *Phoma anethi* [R.A.M., xvii, p. 771] was observed for the first time in Rumania, causing a blackening of apple stems; *F. oxysporum* caused a wilt of bullock's eye plants; black scab [wart disease] of potatoes (*Synchytrium endobioticum*) was recorded [apparently for the first time for Rumania: cf. ibid., xv, p. 252]; and a gummosis of sugar beet was produced by *Bacillus betae* [ibid., xxiii, p. 465].

BONTEA, V.

✓ Rotting of cabbage roots. V. Bontea (*Anal. Inst. Cerc. agron. România*, 1952-3, [1955], 29, 379-427).—The attack on cabbage by *Phoma lingam* and measures taken in Roumania to counteract it are described. Seeds can be disinfected by immersion in water at 50° for 20-25 min., washing with cold water and drying, or, alternatively, by steeping in 0.1% aq.  $HgCl_2$  for  $\frac{1}{2}$  hr. Beds can be disinfected with a 1% solution of 40% formalin two weeks before sowing. (From French summary.) (35 references.) J. S. C.

Title : The Effect of Meteorological Conditions on the Formation, Appearance and Ripening of the Perithecia of Endostigme inaequalis (Cooke) Sydow and on the Dissemination of the Ascospores.

Orig Pub : Phytopathol. Z., 1956, 26, No 4, 233-376.

Abstract : Observations on the manifestation and development of the perithecia were made at Bucharest Agricultural Institute on leaves collected in October and November. Leaves in wire nets were left in the natural conditions of the orchard. From the 15 of December every 15 days one looked

for the appearance of perithecia. An investigation of the processes of formation and ripening of capsules and ascospores began and were repeated every 3 days afterwards, when the first light capsules with uncolored ascospores appeared. Observations for the spread of the ascospores began at the beginning of March and lasted to the end of May. Five years of research indicate that *E. inaequalis* may develop perithecia in the leaves, if the average temperature during 1-2 months has reached  $-3^{\circ}$ , the mean minimum  $-6^{\circ}$  and the mean maximum  $50^{\circ}$ . Perithecia which form in large numbers on falling leaves from the end of August to the end of October are the chief source of spring infection. The ripening process of the ascospores depends on the temperature. Ripening requires an average maximum temperature for 1 month of from 1 to  $12^{\circ}$ , an average minimum of  $-3$  or  $-50^{\circ}$ . The lower the temperature within the limits indicated, the longer the ripening process takes.

Precipitation shows a positive effect on this process. In the orchard the process of ripening lasts from 45 to 50 days. Precipitation and wind play a substantial role in the dissemination of the ascospores. To determine the time for spraying, it is essential to consider the weather conditions, investigate the state of the perithecia in the orchard and, aside from this, to plant additional spores in the laboratory as a control. The bibliography lists 36 titles. -- K.V. Popkova.

... Remarks : The experiments conducted in Romania in 1950-1952 seem to  
have been of the "old" cornflakes varieties at that date.  
When the seeds were dispersed (7% of the grains), the suc-  
cession of the treated seed was higher than from the con-  
trol. This succession was slight (less than 2% of the  
grains), spreading the seeds had a slightly diminishing ef-  
fect. In 1953, the experiments of a number of col-  
lectors showed that in sowing and sowing the seeds are per-  
fected.

TITLE	:	Chemical Compatibility of New Preparations Used for Plant Protection	
ORIG. PUB.	:	An. Inst. cercetari agron., 1957 (1958), 25, No 6, 575-585	
ABSTRACT	:	The following are compatible: Ca-polysulfide (I) with Ca-arsenate (II), hexachlorobenzene, and DDT; Bordeaux mixture (BM) with wettable sulfur (WS) and DDT; WS with hexachlorobenzene and DDT; II and Pb-arsenate (III) with hexachlorobenzene; DDT with parathion (IV); IV with hexachlorobenzene and DDT; hexachlorobenzene with 2,4-D. The following mixtures are incompatible: I with BM, III and IV; BM with hexachlorobenzene. Mixture of WS and BM protects apples against Endostigme inaequalis and Podosphaera leuco- tricha, and grapes against mildew and Oidium. The incom- patible mixture of BM and ISO yields analogous results due to formation of sulfur compounds of Cu.

TITLE : Effectiveness of Domestic Organomercury Preparation in Control of Apple Scab [Endestigme inaequalis (Cooke) Syd.]

ORIG. PUB. : Studii si cercetari biol. Acad. RPR Ser. Biol. veget., 1958, 10, No 4, 393-402

ABSTRACT : In testing a number of organic preparations for control of apple scab, to find a substitute for Bordeaux mixture (BM), the most effective was found to be Mergazin, containing phenylmercurichloride. The quality of fruit, their taste, contents of sugar and vitamine C, are higher than those of apples treated with BM. The preparation can be recommended for control of apple scab, at concentration of 0.2% prior to blossoming, and of 0.1% after blossom. To prevent instances of poisoning, other preparations containing no Hg should be used in the last application.
